

1. Convert the Temperature

You are given a non-negative floating point number rounded to two decimal places celsius, that denotes the temperature in Celsius. You should convert Celsius into Kelvin and

Fahrenheit and return it as an array

`ans = [kelvin, fahrenheit]`. Return the array `ans`. Answers within 10^{-5} of the actual answer

will be accepted. Note that:

- $\text{Kelvin} = \text{Celsius} + 273.15$
- $\text{Fahrenheit} = \text{Celsius} * 1.80 + 32.00$

Example 1:

Input: `celsius = 36.50`

Output: `[309.65000, 97.70000]`

Explanation: Temperature at 36.50 Celsius converted in Kelvin is 309.65 and converted in

Fahrenheit is 97.70. Example 2:

Input: `celsius = 122.11`

Output: `[395.26000, 251.79800]`

Explanation: Temperature at 122.11 Celsius converted in Kelvin is 395.26 and converted in

Fahrenheit is 251.798. Constraints: $0 \leq \text{celsius} \leq 1000$

The screenshot shows a code editor with a file named `main.py`. The code defines a function `convert_temperature(celsius)` that returns a list of Kelvin and Fahrenheit temperatures. It includes two example calls to the function. The output panel shows the results of these calls: `[309.65, 97.7]` and `[395.26, 251.798]`, followed by the message "=== Code Execution Successful ===".

```
main.py
1- def convert_temperature(celsius):
2     kelvin = celsius + 273.15
3     fahrenheit = celsius * 1.80 + 32.00
4     return [kelvin, fahrenheit]
5
6 # Examples
7 print(convert_temperature(36.50)) # Output: [309.65, 97.70]
8 print(convert_temperature(122.11)) # Output: [395.26, 251.798]
9
```

Output

```
[309.65, 97.7]
[395.26, 251.798]

=== Code Execution Successful ===
```

2. Number of Subarrays With LCM Equal to K

Given an integer array `nums` and an integer `k`, return the number of subarrays of `nums` where

the least common multiple of the subarray's elements is `k`. A subarray is a contiguous non-empty sequence of elements within an array. The least common multiple of an array is the

smallest positive integer that is divisible by all the array elements. Example 1: Input: `nums = [3,6,2,7,1]`, `k = 6`

Output: 4

Explanation: The subarrays of nums where 6 is the least common multiple of all the subarray's elements are: - [3,6,2,7,1]

- [3,6,2,7,1]

- [3,6,2,7,1]

- [3,6,2,7,1]

Example 2: Input: nums = [3], k = 2

Output: 0

Explanation: There are no subarrays of nums where 2 is the least common multiple of all the subarray's elements. Constraints:

- $1 \leq \text{nums.length} \leq 1000$
- $1 \leq \text{nums}[i], k \leq 1000$

main.py	Output
<pre>1 from math import gcd 2 from functools import reduce 3 4 def lcm(a, b): 5 return a * b // gcd(a, b) 6 7 def subarrays_with_lcm(nums, k): 8 count = 0 9 n = len(nums) 10 11 for i in range(n): 12 current_lcm = nums[i] 13 for j in range(i, n): 14 current_lcm = lcm(current_lcm, nums[j]) 15 if current_lcm == k: 16 count += 1 17 if current_lcm > k: 18 break 19 20 return count 21 22 # Examples 23 print(subarrays_with_lcm([3,6,2,7,1], 6)) # Output: 4 24 print(subarrays_with_lcm([3], 2)) # Output: 0 25</pre>	<pre>4 0 === Code Execution Successful ===</pre>

51
52     return operations
```

3. Minimum Number of Operations to Sort a Binary Tree by Level

You are given the root of a binary tree with unique values. In one operation, you can choose any two nodes at the same level and swap their values. Return the minimum number of operations needed to make the values at each level sorted in a strictly increasing order. The level of a node is the number of edges along the path between it and the root node. Example 1:

Input: root = [1,4,3,7,6,8,5,null,null,null,9,null,10]

Output: 3

Explanation: - Swap 4 and 3. The 2nd level becomes [3,4]. - Swap 7 and 5. The 3rd level becomes [5,6,8,7]. - Swap 8 and 7. The 3rd level becomes [5,6,7,8]. We used 3 operations so return 3. It can be proven that 3 is the minimum number of operations needed. Example 2:

Input: root = [1,3,2,7,6,5,4]

Output: 3

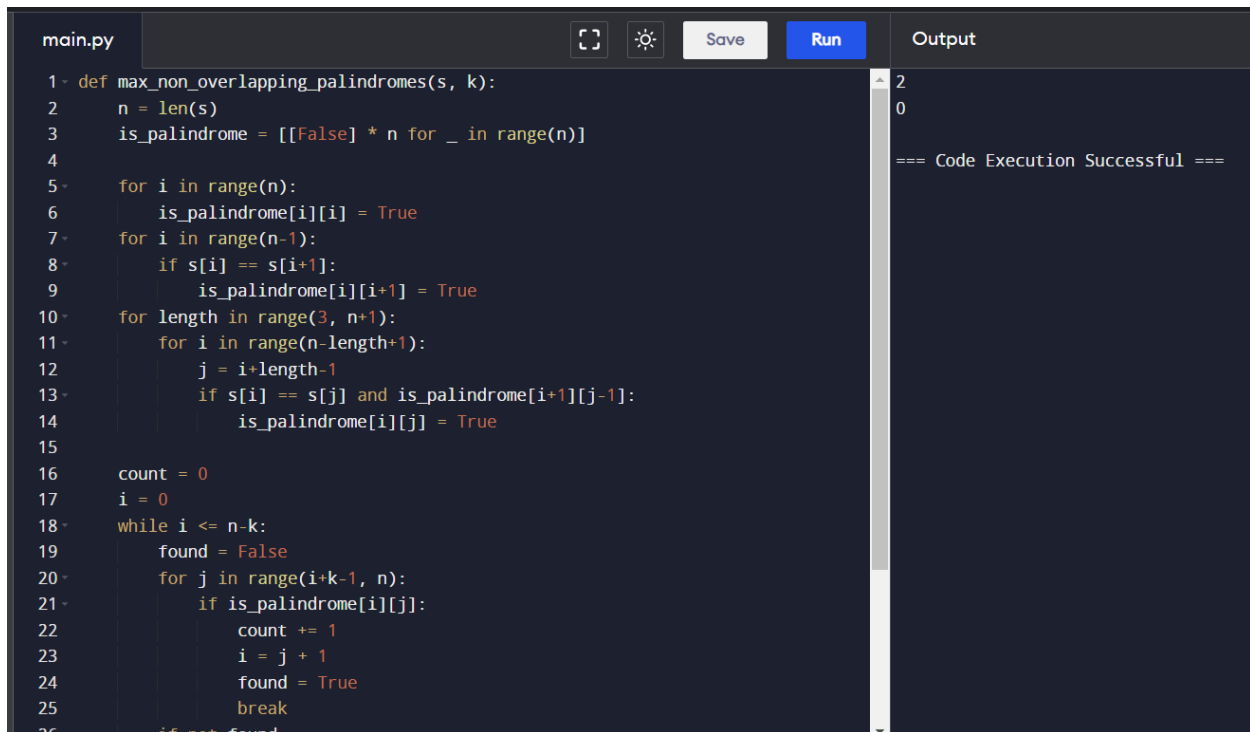

Explanation: - Swap 3 and 2. The 2nd level becomes [2,3]. - Swap 7 and 4. The 3rd level becomes [4,6,5,7]. - Swap 6 and 5. The 3rd level becomes [4,5,6,7]. We used 3 operations so return 3. It can be proven that 3 is the minimum number of operations needed. Example 3:

Input: root = [1,2,3,4,5,6]

Output: 0

Explanation: Each level is already sorted in increasing order so return 0. Constraints:

- The number of nodes in the tree is in the range [1, 105].
- $1 \leq \text{Node.val} \leq 105$
- All the values of the tree are unique.

```
main.py

4. Maximum Number of Non-overlapping Palindrome Substrings

You are given a string *s* and a positive integer *k*. Select a set of non-overlapping substrings

from the string *s* that satisfy the following conditions:

- The length of each substring is at least *k*.
- Each substring is a palindrome. Return the maximum number of substrings in an optimal selection. A substring is a contiguous

sequence of characters within a string. Example 1:

Input: *s* = "abaccdbbd", *k* = 3

Output: 2

Explanation: We can select the substrings underlined in *s* = "abaccdbbd". Both "aba" and

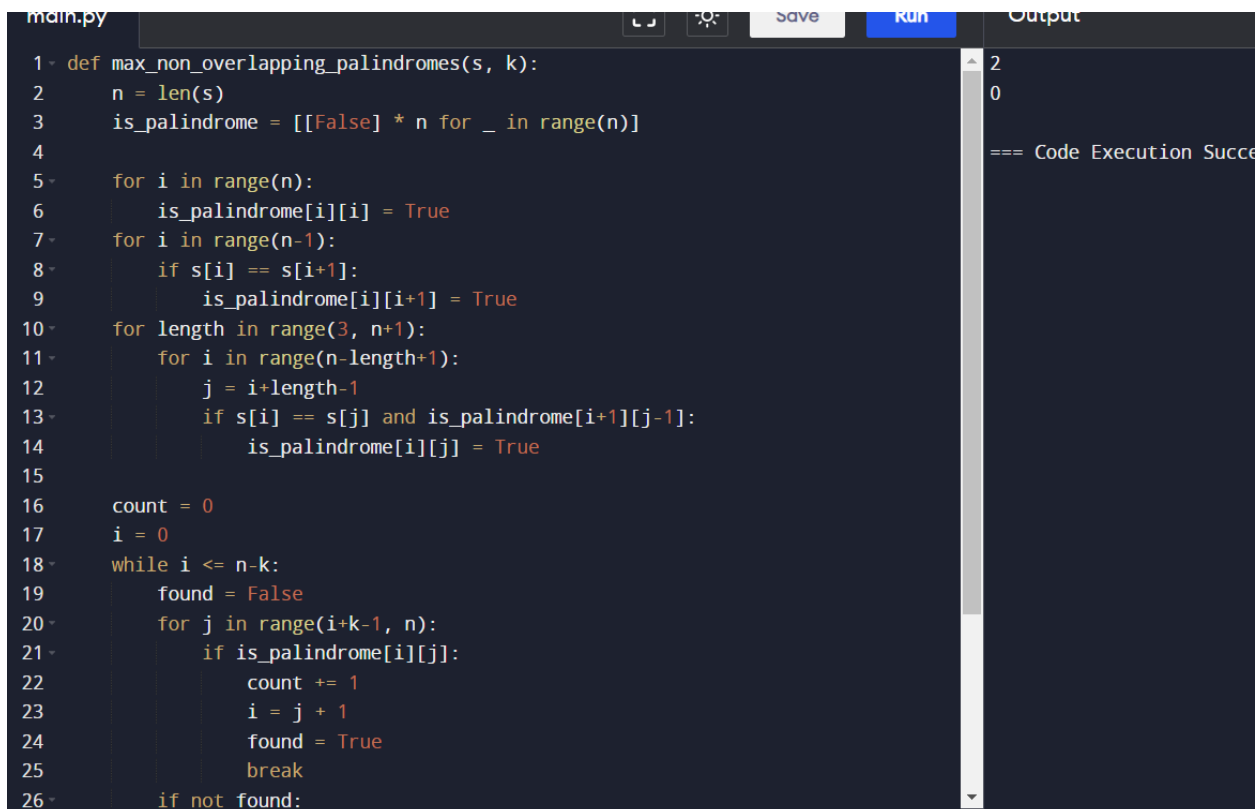

"dbbd" are palindromes and have a length of at least $k = 3$. It can be shown that we cannot find a selection with more than two valid substrings. Example 2:

Input: $s = \text{"adbcda"}, k = 2$

Output: 0

Explanation: There is no palindrome substring of length at least 2 in the string. Constraints:

- $1 \leq k \leq s.length \leq 2000$
- s consists of lowercase English letters.

```
main.py  Save Run Output

5. Minimum Cost to Buy Apples

You are given a positive integer n representing n cities numbered from 1 to n . You are also

given a 2D array $roads$, where $roads[i] = [a_i, b_i, cost_i]$ indicates that there is a bidirectional

road between cities a_i and b_i with a cost of traveling equal to $cost_i$. You can buy apples in any city you want, but some cities have different costs to buy apples. You are given the array $appleCost$ where $appleCost[i]$ is the cost of buying one apple from

city i . You start at some city, traverse through various roads, and eventually buy exactly one apple

from any city. After you buy that apple, you have to return back to the city you started at, but

now the cost of all the roads will be multiplied by a given factor k . Given the integer k , return an array answer of size n where $\text{answer}[i]$ is the minimum total

cost to buy an apple if you start at city i . Example 1:

Input: $n = 4$, $\text{roads} = [[1,2,4],[2,3,2],[2,4,5],[3,4,1],[1,3,4]]$, $\text{appleCost} = [56,42,102,301]$, $k =$

2

Output: $[54,42,48,51]$

Explanation: The minimum cost for each starting city is the following: - Starting at city 1: You take the path $1 \rightarrow 2$, buy an apple at city 2, and finally take the path 2

$\rightarrow 1$. The total cost is $4 + 42 + 4 * 2 = 54$. - Starting at city 2: You directly buy an apple at city 2. The total cost is 42. - Starting at city 3: You take the path $3 \rightarrow 2$, buy an apple at city 2, and finally take the path 2

$\rightarrow 3$. The total cost is $2 + 42 + 2 * 2 = 48$. - Starting at city 4: You take the path $4 \rightarrow 3 \rightarrow 2$ then you buy at city 2, and finally take the

path $2 \rightarrow 3 \rightarrow 4$. The total cost is $1 + 2 + 42 + 1 * 2 + 2 * 2 = 51$. Example 2:

Input: $n = 3$, $\text{roads} = [[1,2,5],[2,3,1],[3,1,2]]$, $\text{appleCost} = [2,3,1]$, $k = 3$

Output: $[2,3,1]$

Explanation: It is always optimal to buy the apple in the starting city. Constraints:

- $2 \leq n \leq 1000$
- $1 \leq \text{roads.length} \leq 1000$
- $1 \leq a_i, b_i \leq n$
- $a_i \neq b_i$
- $1 \leq \text{cost}_i \leq 10^5$
- $\text{appleCost.length} == n$
- $1 \leq \text{appleCost}[i] \leq 10^5$
- $1 \leq k \leq 100$
- There are no repeated edges.

```

main.py  save  run  Output
1 import heapq
2
3 def min_cost_to_buy_apples(n, roads, appleCost, k):
4     graph = [[] for _ in range(n)]
5     for a, b, cost in roads:

6. Customers With Strictly Increasing Purchases

SQL Schema

Table: Orders

Column Name	Type
order_id	int
customer_id	int
order_date	date
price	int

order_id is the primary key for this table. Each row contains the id of an order, the id of customer that ordered it, the date of the order, and its price. Write an SQL query to report the IDs of the customers with the total purchases strictly

increasing yearly. ● The total purchases of a customer in one year is the sum of the prices of their orders in

that year. If for some year the customer did not make any order, we consider the total

purchases 0. ● The first year to consider for each customer is the year of their first order. ● The last year to consider for each customer is the year of their last order. Return the result table in any order. The query result format is in the following example. Example 1:

Input:

Orders table:

order_id	customer_id	order_date	price
1	1	2019-07-01	1100
2	1	2019-11-01	1200
3	1	2020-05-26	3000
4	1	2021-08-31	3100
5	1	2022-12-07	4700
6	2	2015-01-01	700
7	2	2017-11-07	1000
8	3	2017-01-01	900
9	3	2018-11-07	900

Output:

customer_id
1

Explanation:

Customer 1: The first year is 2019 and the last year is 2022

- 2019: 1100 + 1200 = 2300

- 2020: 3000

- 2021: 3100

- 2022: 4700

We can see that the total purchases are strictly increasing yearly, so we include customer 1 in the answer. Customer 2: The first year is 2015 and the last year is 2017

- 2015: 700

- 2016: 0

- 2017: 1000

We do not include customer 2 in the answer because the total purchases are not strictly

increasing. Note that customer 2 did not make any purchases in 2016. Customer 3: The first year is 2017, and the last year is 2018

- 2017: 900

- 2018: 900

We can see that the total purchases are strictly increasing yearly, so we include customer 1 in the answer.

main.py	Save	Run	Output
<pre>1 def count_unequal_triplets(nums): 2 n = len(nums) 3 count = 0 4 5 for i in range(n-2): 6 for j in range(i+1, n-1): 7 for k in range(j+1, n): 8 if nums[i] != nums[j] and nums[i] != nums[k] and nums[j] != nums[k]: 9 count += 1 10 11 return count 12 13 # Examples 14 print(count_unequal_triplets([4,4,2,4,3])) # Output: 3 15 print(count_unequal_triplets([1,1,1,1,1])) # Output: 0 16</pre>			<pre>3 0 === Code Execution Successful</pre>

7. Number of Unequal Triplets in Array

You are given a 0-indexed array of positive integers `nums`. Find the number of triplets (i, j, k)

that meet the following conditions:

- $0 \leq i < j < k < \text{nums.length}$
- `nums[i]`, `nums[j]`, and `nums[k]` are pairwise distinct. In other words, `nums[i] != nums[j]`, `nums[i] != nums[k]`, and `nums[j] !=`

`nums[k]`. Return the number of triplets that meet the conditions. Example 1:

Input: `nums = [4,4,2,4,3]`

Output: 3

Explanation: The following triplets meet the conditions: - (0, 2, 4) because $4 \neq 2 \neq 3$

- (1, 2, 4) because $4 \neq 2 \neq 3$

- (2, 3, 4) because $2 \neq 4 \neq 3$

Since there are 3 triplets, we return 3. Note that (2, 0, 4) is not a valid triplet because $2 > 0$. Example 2:

Input: `nums = [1,1,1,1,1]`

Output: 0

Explanation: No triplets meet the conditions so we return 0. Constraints:

- $3 \leq \text{nums.length} \leq 100$
- $1 \leq \text{nums}[i] \leq 1000$

8. Closest Nodes Queries in a Binary Search Tree

You are given the root of a binary search tree and an array queries of size n consisting of positive integers. Find a 2D array answer of size n where `answer[i] = [mini, maxi]`:

- mini is the largest value in the tree that is smaller than or equal to `queries[i]`. If a such value does not exist, add -1 instead.
- maxi is the smallest value in the tree that is greater than or equal to `queries[i]`. If a

such value does not exist, add -1 instead. Return the array answer. Example 1:

Input: `root = [6,2,13,1,4,9,15,null,null,null,null,null,14]`, `queries = [2,5,16]`

Output: `[[2,2],[4,6],[15,-1]]`

Explanation: We answer the queries in the following way: - The largest number that is smaller or equal than 2 in the tree is 2, and the smallest number

that is greater or equal than 2 is still 2. So the answer for the first query is [2,2]. - The largest number that is smaller or equal than 5 in the tree is 4, and the smallest number

that is greater or equal than 5 is 6. So the answer for the second query is [4,6]. - The largest number that is smaller or equal than 16 in the tree is 15, and the smallest number

that is greater or equal than 16 does not exist. So the answer for the third query is [15,-1]. Example 2:

Input: `root = [4,null,9]`, `queries = [3]`

Output: `[[-1,4]]`

Explanation: The largest number that is smaller or equal to 3 in the tree does not exist, and the smallest number that is greater or equal to 3 is 4. So the answer for the query is [-1,4]. Constraints:

- The number of nodes in the tree is in the range [2, 105].
- $1 \leq \text{Node.val} \leq 106$

- $n == \text{queries.length}$
- $1 \leq n \leq 105$
- $1 \leq \text{queries}[i] \leq 106$

main.py	Output
<pre> 1 def find_prefix_common_array(A, B): 2 n = len(A) 3 prefix_common = [0] * n 4 common_elements = set() 5 6 for i in range(n): 7 common_elements.add(A[i]) 8 if B[i] in common_elements: 9 prefix_common[i] = prefix_common[i-1] + 1 if i > 0 else 1 10 else: 11 prefix_common[i] = prefix_common[i-1] if i > 0 else 0 12 13 return prefix_common 14 15 # Examples 16 print(find_prefix_common_array([1,3,2,4], [3,1,2,4])) # Output: [0,2,3,4] 17 print(find_prefix_common_array([2,3,1], [3,1,2])) # Output: [0,1,3] 18 </pre>	<pre> [0, 1, 2, 3] [0, 0, 1] === Code Execution Successful </pre>

9. Minimum Fuel Cost to Report to the Capital

There is a tree (i.e., a connected, undirected graph with no cycles) structure country network consisting of n cities numbered from 0 to $n - 1$ and exactly $n - 1$ roads. The capital city is city

0. You are given a 2D integer array `roads` where `roads[i] = [ai, bi]` denotes that there exists a bidirectional road connecting cities `ai` and `bi`. There is a meeting for the representatives of each city. The meeting is in the capital

city. There is a car in each city. You are given an integer `seats` that indicates the number of

seats in each car. A representative can use the car in their city to travel or change the car and

ride with another representative. The cost of traveling between two cities is one liter of fuel. Return the minimum number of liters of fuel to reach the capital city. Example 1:

Input: `roads = [[0,1],[0,2],[0,3]]`, `seats = 5`

Output: 3

Explanation: - Representative1 goes directly to the capital with 1 liter of fuel. - Representative2 goes directly to the capital with 1 liter of fuel. - Representative3 goes directly to the capital with 1 liter of fuel.

It costs 3 liters of fuel at minimum. It can be proven that 3 is the minimum number of liters of fuel needed. Example 2:

Input: `roads = [[3,1],[3,2],[1,0],[0,4],[0,5],[4,6]]`, `seats = 2`

Output: 7

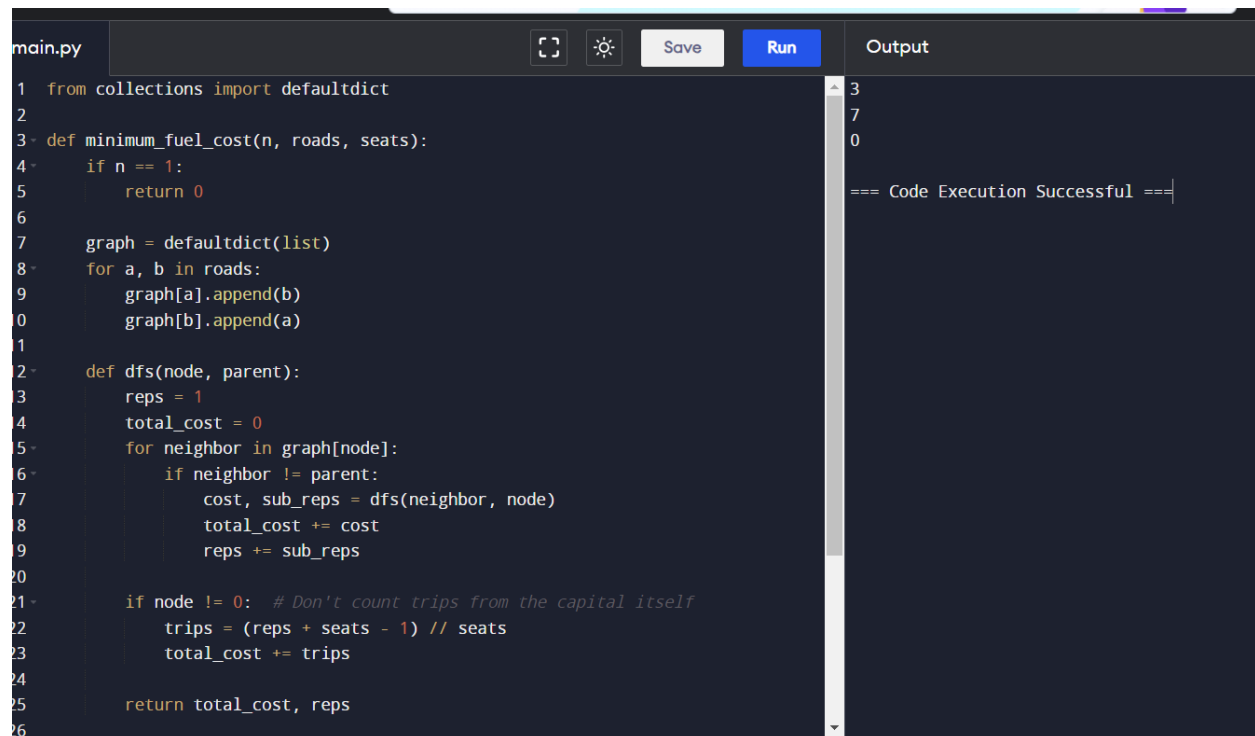

Explanation: - Representative2 goes directly to city 3 with 1 liter of fuel. - Representative2 and representative3 go together to city 1 with 1 liter of fuel. - Representative2 and representative3 go together to the capital with 1 liter of fuel. - Representative1 goes directly to the capital with 1 liter of fuel. - Representative5 goes directly to the capital with 1 liter of fuel. - Representative6 goes directly to city 4 with 1 liter of fuel. - Representative4 and representative6 go together to the capital with 1 liter of fuel. It costs 7 liters of fuel at minimum. It can be proven that 7 is the minimum number of liters of fuel needed. Example 3:

Input: roads = [], seats = 1

Output: 0

Explanation: No representatives need to travel to the capital city. Constraints:

- $1 \leq n \leq 105$
- $\text{roads.length} == n - 1$
- $\text{roads}[i].\text{length} == 2$
- $0 \leq a_i, b_i < n$
- $a_i \neq b_i$
- roads represents a valid tree.
- $1 \leq \text{seats} \leq 105$

10. Number of Beautiful Partitions

You are given a string s that consists of the digits '1' to '9' and two integers k and $minLength$. A partition of s is called beautiful if:

- s is partitioned into k non-intersecting substrings.
- Each substring has a length of at least $minLength$.
- Each substring starts with a prime digit and ends with a non-prime digit. Prime digits

are '2', '3', '5', and '7', and the rest of the digits are non-prime. Return the number of beautiful partitions of s . Since the answer may be very large, return it

modulo $10^9 + 7$. A substring is a contiguous sequence of characters within a string. Example 1:

Input: $s = "23542185131"$, $k = 3$, $minLength = 2$

Output: 3

Explanation: There exists three ways to create a beautiful partition: "2354 | 218 | 5131"

"2354 | 21851 | 31"

"2354218 | 51 | 31" Example 2:

Input: $s = "23542185131"$, $k = 3$, $minLength = 3$

Output: 1

Explanation: There exists one way to create a beautiful partition: "2354 | 218 | 5131". Example 3:

Input: $s = "3312958"$, $k = 3$, $minLength = 1$

Output: 1

Explanation: There exists one way to create a beautiful partition: "331 | 29 | 58". Constraints:

- $1 \leq k$, $minLength \leq s.length \leq 1000$
- s consists of the digits '1' to '9'
